06 · Phasing

Four phases. The sequence is deliberate: the commercial conditions are settled before any platform money is spent, and the pilot builds the real product rather than a demonstration of it.

Phase 0 — Agreement (now)

What happens. Dupoin and MMFX settle the commercial terms in `05` — the override, the term, portability, and the three conditions. MMFX scopes the short foundation course.

Exit criterion. Condition 1 confirmed in writing: Dupoin commits to a sub-IB-level data feed including lots traded, with a refresh cadence, and supplies baseline survival and activity figures from the existing IB book.

Why this gates everything. Phase 1 is a substantial engineering investment made ahead of any revenue. MMFX will make it — but not against an unverifiable outcome. If the data does not exist, neither party can tell whether this worked, and the arrangement should not start.

Phase 1 — Build

What happens. The existing single-brand product is made multi-tenant:

- Tenant scoping across member data, with a full access-control pass
- Branding layer: per-tenant theme, logo, custom domain, email sender, document templating
- Per-tenant funnel configuration: broker routing, referral links, trial length
- Per-tenant feature toggles
- The upload-and-publish studio for IB content
- Tenant-scoped administration and analytics
- The neutral engine brand for the TradingView suite
- Production of the short foundation course

What is deliberately not built. Per-tenant content authoring beyond upload-and-publish, the IB-facing portal, server-side conversion events, and the multi-tenant ad-account structure. These are Phase 3, once the pilot has shown the model works.

Risk, stated plainly. This phase is built before the thesis is proven. That is a considered decision: a co-branded pilot on the existing MMFX desk would have tested a proxy, not the product, and would have produced a result neither party could trust. The mitigation is Phase 0 — the conditions are settled first, and the build scope is held to what three desks actually need.

Phase 2 — Pilot

Three IBs minimum. Sixty to ninety days.

Three genuinely branded desks on shared infrastructure, each with their own content mix, their own domain and their own traders. Real acquisition, real funded accounts, real volume.

Selection. IBs with an existing audience and no product — that is the profile this is built for, and the profile where the effect should be clearest. Ideally in different markets, to avoid the overlap question in `05`.

What is measured.

Metric	Why
Funded accounts per IB	Does the funnel convert
Lots per funded account per month	Does the desk increase activity
90-day account survival vs Dupoin's baseline	**The core claim.** Does the desk keep accounts alive
Trial-to-funded conversion rate	Funnel efficiency
Cost per funded account, where paid media is used	Whether Tier 3 can ever pay for itself
Support load per tenant	Whether the model scales operationally

Success. Survival and lots per account measurably above Dupoin's baseline, at a support and infrastructure cost per tenant that leaves the override profitable at scale.

Failure is also a valid outcome. If the desk does not move survival, that is worth knowing after three tenants rather than thirty, and both parties should be able to say so.

Phase 3 — Scale

What happens. Onboarding beyond the pilot cohort, against the minimum-volume threshold and dormancy terms in `05`. The deferred build items come in as volume justifies them: sub-IB attribution reporting, the IB-facing portal, server-side conversion events, the short-form pipeline, and the multi-tenant ad-account structure that Tier 3 needs.

Tier 3 — MMFX running paid media — is entered deliberately and with a small number of IBs, once Tier 1 has demonstrated that the desk produces volume without it.
